

Summary of this week

- This week, you learned:
 - How to generalize linear state-state model to describe nonlinear systems.
 - How to apply two assumptions to derive the extended Kalman filter from the generic Gaussian sequential-probabilistic-inference solution.
 - How to write Octave code to implement EKF for a nontrivial nonlinear state-estimation problem.
 - How to interpret some results from executing this code.

Where from here?

- Next week, you will learn:
 - Sigma-point approach to approximating statistics of a RV passed through a nonlinear function.
 - How to apply sigma-point approach to general Gaussian sequential-probabilistic-inference solution to derive the sigma-point Kalman filter.
 - How to write Octave code to implement SPKF for the nontrivial nonlinear spring-mass-damper system.
 - How to interpret the SPKF results and compare with the EKF results.
